Abstract

In this technical note we present the multi-purpose atmospheric chemistry model MECCA. Owing to its versatility and modular structure, it can be used for tropospheric as well as stratospheric chemistry calculations. Extending the code to other domains (e.g. mesospheric or oceanic chemistry) is easily possible. MECCA contains a comprehensive atmospheric reaction mechanism that currently includes: 1) the basic O_3 , CH_4 , HO_x , and NO_x chemistry, 2) non-methane hydrocarbon (NMHC) chemistry, 3) halogen (Cl, Br, I) chemistry, and 4) sulfur chemistry. Not only gas-phase chemistry but also aqueous-phase and heterogeneous reactions are considered. Arbitrary subsets of the comprehensive mechanism can be selected according to the research objectives. The program code resulting from the chemical mechanism can easily be used in any kind of model, from a simple box model to a sophisticated global general circulation model.

1. Introduction

In the past, many computer models of atmospheric chemistry have been developed. Since each was aimed at a particular goal, they vary strongly in complexity and efficiency. Often they encompass the basic chemistry of O_3 , CH_4 , HO_x ($=\text{OH}+\text{HO}_2$), and NO_x ($=\text{NO}+\text{NO}_2$). Some also include a more detailed mechanism for higher hydrocarbons, halogens, sulfur, or other species. There are box and column models as well as two- or three-dimensional regional and global models. Chemical mechanisms have been developed for the gas phase and also for aerosols and cloud droplets. The focus is usually on either stratospheric or tropospheric chemistry. The chemistry codes are intertwined with meteorological models that supply parameters such as radiation, temperature, pressure, humidity, and wind fields.

As part of the model development, one often needs to combine several chemistry mechanisms. Another frequently occurring task is coupling chemical mechanisms to a meteorological model, for example, for an intercomparison. Unfortunately, these are

both time-consuming tasks due to different approaches and incompatibilities between the codes. Also, it is often complicated because there is no clear separation between the meteorological and the chemical part of the model, and such a setup is sensitive to errors.

- 5 In our implementation we apply a new approach aimed at avoiding the above mentioned problems. Here, we present the new comprehensive atmospheric chemistry module MECCA (Module Efficiently Calculating the Chemistry of the Atmosphere).

2. Model Description

The main features of MECCA, as described in detail below, are:

- 10 *Chemical flexibility.* The chemical mechanism contains a large number of reactions from which the user can select a custom-designed subset. It is easy to adjust the mechanism, e.g. according to the latest kinetic insights.

Numerical flexibility. The numerical integration method can be chosen according to individual requirements of the stiff set of differential equations (efficiency, stability, accuracy, precision).

- 15 *Modularity.* Due to its modular structure and strict adherence to the MESSy standard (explained below), the code can be easily coupled to other meteorological base models (e.g. box models, 1-dimensional column models, or 3-dimensional models).

Portability. The Fortran95 code is written in a portable way to allow its use on different platforms (e.g. Linux, Unix).

- 20 *Availability.* The code is freely available to the scientific community.

2.1. Chemical flexibility

In the current version of MECCA, five previously published chemical mechanisms have been combined and updated. Tropospheric hydrocarbon chemistry is adopted from von Kuhlmann et al. (2003). The chemistry of the stratosphere is based on the model

of Steil et al. (1998) and the Mainz Chemical Box Model (Meilinger, 2000). Tropospheric halogen chemistry is taken from Sander and Crutzen (1996) and von Glasow et al. (2002). The current mechanism contains 116 species and 295 reactions in the gas phase, and 90 species and 285 reactions in the aqueous phase. The rate coefficients are updated according to Sander et al. (2003), Atkinson et al. (2003), and other references. A detailed listing of reactions, rate coefficients, and their references can be found in the electronic supplement at <http://www.copernicus.org/EGU/acp/acpd/4/7167/acpd-4-7167-sp.zip>. It is both possible and desirable to add reactions to the mechanism in the near future. However, for computational efficiency, it is normally not required to integrate the whole mechanism. Therefore we have implemented a method by which the user can easily create their own custom-made chemical mechanism. Each reaction has several labels to categorize it. For example, the labels *Tr* and *St* indicate reactions relevant in the troposphere and the stratosphere, respectively. These labels are not mutually exclusive. Many reactions need to be considered for both layers. There are also labels for the phase in which they occur (gas or aqueous phase) and for the elements that they contain (e.g. Cl, Br, and I for reactions of the halogen species). It is also possible to create new labels for specific purposes. For example, all reactions with the label *Mbl* are part of a reduced mechanism for the marine boundary layer. Using a Boolean expression based on these labels, it is possible to create custom-made subsets of the comprehensive mechanism. The main advantage of maintaining a single comprehensive mechanism is that new reactions and updates of rate coefficients need to be included only once so that they are immediately available for all subsets.

2.2. Numerical flexibility

Once a subset of the full mechanism has been selected as described above, the kinetic preprocessor (kpp) software (Damian et al., 2002, Sandu and Sander, in preparation,

2004¹) is used to transform the chemical equations into Fortran95 code. From a numerical point of view, atmospheric chemistry is a challenge due to the coexistence of very stable (e.g. CH₄) and very reactive species, e.g. O(¹D). To overcome this so-called stiffness issue, robust numerical solvers are necessary. kpp provides several solvers with either manual or automatic time step control. Although computationally more demanding, the latter is best suited for the most difficult stiffness problems e.g. associated with multiphase chemistry. For each individual application, it is necessary to balance the advantages and disadvantages regarding efficiency, stability, accuracy, and precision. We found that for most of our chemical mechanisms, Rosenbrock solvers of 2nd or 3rd order (Sandu et al., 1997) work best. However, we wish to stress that it may be necessary to test other solvers as well to achieve the best performance for a given set of equations. Fortunately, switching between solvers is easy with kpp and does not require any reprogramming of the chemistry scheme.

2.3. Modularity

An important feature of MECCA is its modular structure. Without any changes to the code, it is possible to link MECCA to different meteorological base models. This is achieved by strict adherence to the MESSy standard, as described by Jöckel et al. (2004). A major advantage of this modularity is that it allows extensive testing of the chemical mechanism in a box model before starting computationally expensive global model runs. The box models are easy to handle. All that is needed is to supply constant values or a time series for temperature, pressure, humidity, and J-values of photolysis reactions. At present, MECCA chemistry modules have been coupled to three box models and a 3-D global general circulation model. Preliminary results are shown in Sect. 3.

2.4. Portability

To ensure maximum portability, the code is written in standard Fortran95 (ISO/IEC-1539-1). It does not depend on any compiler-specific language extensions. We have checked this using the fortran analyser forcheck (<http://www.forcheck.nl/>). The system

5 requirements for the MECCA installation are:

- A Unix or Linux operating system including the standard tools (tcsh, gawk, sed, make, etc.)
- A Fortran95 compiler (So far, we have compiled MECCA successfully with GNU, Lahey, Intel, Compaq, IBM, and NEC compilers)
- 10 – The kpp software (available in the electronic supplement and also at <http://www.cs.vt.edu/~asandu/Software/KPP>)
- Optional: The netcdf library to obtain output files in netcdf format (without it, output is made to ascii files)
- Optional: LaTeX to print a table containing the rate coefficients of the current
15 reaction mechanism

2.5. Availability

We believe that the scientific community will benefit most if MECCA is free code. Therefore we have made MECCA available under the GNU public licence (<http://www.gnu.org/copyleft/gpl.html>). We hope that this leads to a wide acceptance of MECCA as an
20 addition or alternative to commercial software like Facsimile (Curtis and Sweetenham, 1987). We also hope for feedback from the community to maintain state-of-the-art software and chemical kinetics information. The current version is provided in the electronic supplement together with a user manual which describes how to install, execute, and modify MECCA on your computer. Future updates will be provided for download
25 at our web page: <http://www.mpch-mainz.mpg.de/~sander/messy/mecca/>.

3. Results and discussion

To illustrate its versatility, we present here some sample applications for MECCA.

3.1. Halogen chemistry in the marine boundary layer

Since the reactions of our comprehensive multiphase chemistry model MOCCA (Sander and Crutzen, 1996; Vogt et al., 1996) have been implemented in MECCA, a comparison of these two models is a good start to validate MECCA. We have written a box model that provides typical conditions (temperature, pressure, humidity, sea-salt aerosol, and J-values of photolysis reactions) of the marine boundary layer at mid-latitude in spring, similar to MOCCA. From the comprehensive set of chemical reactions in MECCA, we discarded those that occur only in the stratosphere as well as those of higher hydrocarbons ($\geq C_2$). Some results of both model runs are shown in Fig. 1. The similarity is not surprising, given the similar reaction mechanisms. It shows that MECCA with its kpp integrator is capable of handling the very stiff set of differential equations and of reproducing the results of MOCCA. Minor differences result from updated rate constants and slightly different boundary conditions.

3.2. Stratospheric chemistry

Grenfell et al. (submitted, 2004)² have coupled MECCA to a stratospheric box model to quantify ozone loss via chemical cycles and pathways. Some results from a sensitivity study of theirs, involving the effect of increased water, chlorine and bromine upon stratospheric ozone, are shown in Fig. 2. For these calculations, tropospheric reactions were excluded.

3.3. Modeling the field campaign MINATROC

MECCA can also be used to compare field data with model results. De Reus et al. (in preparation, 2004)³ used measured data of long-lived species from the MINATROC campaign as input for MECCA. For each set of measurements, the model was run until HCHO concentrations reached a steady state. The results were compared to observed values of HCHO as shown in Fig. 3. Only for 4 out of 272 data points is the discrepancy between measured and modeled data larger than a factor of two, which is about the total uncertainty of all measured parameters used as input for the model calculations. Obviously, much of the measured variability in HCHO is associated with irregular ambient conditions, which is difficult to capture by a model. Nevertheless, the comparison in Fig. 3 suggests that systematic model biases are low.

3.4. Global chemistry

Box models allow quick sensitivity studies of the selected chemical mechanism. Often, however, regional or global studies are desired. Therefore we have coupled the MECCA mechanism via the MESSy interface to the general circulation model (GCM) ECHAM5 (<http://www.mpimet.mpg.de/en/extra/models/echam/echam5.php>). In this setup, MECCA calculates all chemical processes, whereas the GCM integrates the non-chemical sources and sinks (e.g. advection, convection, dry deposition, sedimentation, ...) of these species. In Fig. 4 we show results to illustrate how the tropospheric halogen chemistry described above can also be applied on a global scale (Kerkweg et al., in preparation, 2004⁴). Of course, other subsets of the MECCA mechanism (e.g.

stratospheric chemistry or very condensed schemes for extended climate studies) can also be selected in global applications.

4. Conclusions

In this technical note, we present the versatile model MECCA. Its chemical and numerical flexibility, its modularity, and its portability make it an ideal tool for many applications. The scheme is publicly available for atmospheric chemistry and climate research.

Acknowledgements. We would like to thank R. von Glasow and R. von Kuhlmann for making their kpp chemistry codes available. We are grateful to A. Sandu for providing the kpp software which facilitated the development of MECCA.

Fig. 4. Sample plot showing preliminary results of chloride enrichment factors $EF(\text{Cl})$ in near-surface sea-salt aerosol. The calculations were made with the MECCA chemistry coupled to ECHAM5/MESSy. Chloride deficits (i.e. values of $EF(\text{Cl}) < 1$) occur where acid displacement has transformed aerosol chloride into gaseous HCl. This occurs mainly in areas where sea-salt aerosol mixes with anthropogenically produced acids such as H_2SO_4 and HNO_3 .
